The overturning safety factor (OSF) is the sum of resisting moments divided by the sum of overturning moments. Most codes require that this factor be greater than 1.5.

For assessments related to overturning and sliding stability, irrespective of the building risk and seismic design categories, seeing a factor of safety of 1.5 has been a norm for structural ...

In this tutorial, we will provide you with a simple guide on how to calculate overturning moment, what it is, how it's calculated, and the factor of safety.

A: The factor of safety against overturning is important because it provides a measure of the stability of a structure against overturning. A structure with a low factor of safety against ...

Safety Factors in Overturning Calculations: Discusses safety factors involved in overturning calculations, emphasizing the balance between load conditions and supporting capacity.

Per ACI 318, 10.5.4 & 7.12, This will be enforced for both top and bottom bars together (rather than each separately) as explained in Section 4.10.3. Per ACI 318, 10.5.4, Minimum number of bars to meet s ...

To prevent overturning of portrait vertical packaging, anti-overturn support and hundreds of kilograms of counterweight are required, which is difficult to obtain at a project ... Using these experimental data, a ...

You setup the geometry of your structure so that it will not overturn (or slide) with a safety factor. This could be 1.3 or 1.5 depending on project specific items.
